Explaining Singly-linked-list repr.

In singly-linked-list.  
typedef struct Node {

DATA-TYPE data;

struct Node\* next;

} Node;

In here:

typedef struct Stack {

Node\* top; // pointer to the current node

Node\* stack;

} Stack;

functions:

① initializeStack()

Stack->top = NULL;

Stack->stack = initialize();

② void push(Stack\* stack, DATA-TYPE value)

Stack->stack = insertEnd(stack->stack, value);

③ DATA-TYPE pop(Stack\* stack)

Special case: empty i.e. isEmpty(stack->stack)

return -1;

General case:

④ peek(Stack\* stack)

if (!isEmpty(stack->stack))

return -1;

return showEndData(stack->stack);

⑤ displayStack(Stack\* stack)

displayList(stack->stack);

⑥ deleteStack(Stack\* stack) // delete all stack

① deleteAll(stack->stack)

top = NULL
